

# Snapshot Analytics & Pipeline Waterfall

A complete implementation guide for point-in-time pipeline analysis in Data Cloud and Tableau Next

# Why This Matters

Sales leaders need to answer a deceptively hard question: **Why is our pipeline different today than it was last month?** Standard Salesforce reports show current state. They cannot show movement — what came in, what grew, what churned out, what closed.

Answering that question requires two things: **point-in-time snapshots** of opportunity data, and a **waterfall visualization** that breaks the delta between two dates into its component movements.

Final result: Pipeline Waterfall dashboard with date parameters — gray total bars, green inflow bars, red outflow bars. All bars render from zero; the CASE formula handles directionality.

# Prerequisites

- Data Cloud provisioned and connected to your Salesforce org

Note: Data Cloud was rebranded to **Data 360** in October 2025. You may see "Data 360" in the UI — the features and navigation paths are identical.

- Tableau Next enabled

- Data Cloud Admin access to create Data Streams, Data Lake Objects, and Data Transforms
- Tableau Next Creator license
- A configured Data Space in Data Cloud
- A live Salesforce CRM Data Stream connected to the Opportunity object

# Architecture Overview

The pipeline waterfall requires a **Snapshot Store** — a single Data Lake object containing one row per opportunity *per snapshot date*. A **Batch Data Transform** runs daily, stamping that day's date onto every opportunity and writing it into the store. The Tableau Next semantic model then compares two selected dates to compute each waterfall bar.

## PART 1 OF 2

Build the Snapshot Store — add the cross-join key, create the consolidated DLO, and run the daily Batch Data Transform.

# Step 1 — Add CrossJoinKey to Your Opportunity DLO

Before building the Snapshot Store, add a formula field to your source Opportunity DLO. This carries a constant value of **1** through the batch transform, enabling the cross-join to the Waterfall Labels table in the semantic model.

Navigate to your Opportunity DLO: Data Cloud Setup → **Data Lake Objects** → [your Opportunity DLO] → **Fields** → **New Field**

| Field Label  | Field API Name  | Data Type | Formula / Default |
|--------------|-----------------|-----------|-------------------|
| CrossJoinKey | CrossJoinKey__c | Number    | 1                 |

**Why this field?** The SDM cross-join between the Snapshot Store and the Waterfall Labels table requires a shared key where every row on both sides carries the same value. A static **1** on every opportunity row guarantees every row joins to every label row — producing all 9 bars.

Also confirm these fields exist and note their exact API names — every formula downstream references them verbatim:

| Required Field   | Common API Names       |
|------------------|------------------------|
| Opportunity ID   | Id__c                  |
| Revenue / Amount | Amount__c              |
| Stage            | Stage__c, StageName__c |

**Note on waterfall bars 2–8:** These bars can be driven by either **Opportunity Type** or **Stage name**. If your org only has one Type value (e.g. all opps = '**New Business**'), use Stage name instead — it produces more meaningful breakdowns. Confirm what distinct values exist before building formulas.

## Step 2 — Create the Snapshot Store DLO

Create a new, standalone Data Lake Object with only the fields needed for the waterfall. This keeps the Snapshot Store lean and purpose-built.

### 1 New Data Lake Object

Data Cloud Setup → **Data Lake Objects** → **New**. Name it **Snapshot Store**. Add these six fields:

| Field Label   | Field API Name          | Data Type  | Notes                                    |
|---------------|-------------------------|------------|------------------------------------------|
| Id            | <b>Id__c</b>            | Text (255) | Opportunity record ID                    |
| Amount        | <b>Amount__c</b>        | Number     | Opportunity revenue value                |
| Stage         | <b>Stage__c</b>         | Text (255) | Opportunity stage name                   |
| Snapshot Date | <b>Snapshot_Date__c</b> | Date       | Stamped by the daily transform           |
| Compound Id   | <b>Compound_Id__c</b>   | Text (255) | Upsert key: OpportunityId + SnapshotDate |
| CrossKeyJoin  | <b>CrossKeyJoin__c</b>  | Number     | Static 1 — enables SDM cross-join        |

**Why Snapshot Date?** Without a date stamp on each row, the DLO only holds current-state data. Snapshot Date lets you filter to any point in time and compare two dates in the semantic model. It's what turns a flat opportunity list into a time-series store.

**Why Compound Id?** Each daily run writes a new snapshot for every opportunity. The upsert write mode needs a unique key per row to distinguish "new snapshot row for the same opportunity" from "update to an existing row". Concatenating **OpportunityId** + **SnapshotDate** gives a key that is unique across both dimensions.

### 2 Add Snapshot Store to your Data Space

Data Spaces → [your data space] → **Add Objects** → **Snapshot Store**. The DLO must be in a Data Space to be visible in Tableau Next.

Snapshot Store DLO showing the six essential fields: Amount, Compound Id, CrossKeyJoin, Id, Snapshot Date, Stage.

## Step 3 — Build the Batch Data Transform

Navigation: Data Cloud Setup → **More** (top of left nav) → **Data Transforms** → **New** → **Batch Data Transform**

**Navigation note:** The menu item is **Data Transforms**, not "Data Transformations". Direct URL navigation (</lightning/o/DataTransformation/home>) returns a permissions error — navigate via the **More menu** only.

Name it: **Snapshot Opportunity Pipeline**. The canvas uses a recipe-style node editor — the same visual language as CRMA Data Recipes:

- **Teal circle** = source (data input)
- **Blue star** = transform (formula / calculated columns)
- **Purple circle** = output (write node)

*Batch transform canvas: Opportunity DLO (teal) → Transform 0 (blue star) → Write Node (purple).*

### 3a — Source Node

Click the teal source node. In the left panel, confirm the API name of your Opportunity DLO. This is the object the transform reads from on every run.

**Field selection:** Select only the fields needed for the waterfall: **Id**, **Amount**, **Stage**, and **CrossJoinKey**. Including all fields from a large Opportunity DLO adds unnecessary processing time. Any **kQ\_** prefixed fields auto-generated by Data Cloud on the source DLO can be excluded — the Snapshot Store manages its own upsert key via Compound Id.

### 3b — Transform Node (Calculated Fields)

Click the blue star node. In the left panel, add two calculated columns:

#### Calculated Columns

#### Transform node

```
Column 1 — Snapshot Date
Name: Snapshot Date
Formula: current_date()
Type: Date
Column 2 — Compound Id
Name: Compound Id
Formula: concat(Id__c, Snapshot_Date)
Type: Text
```

**Why these fields?** The Opportunity DLO holds current records but no date stamp. The transform injects two fields on every run: **Snapshot Date** pins today's date to every row, creating the time dimension; **Compound Id** combines the opportunity ID with that date to produce a row-level upsert key. Together they convert a flat opportunity list into a growing time-series store — each daily run adds a new dated layer without overwriting history.

Replace **Id\_\_c** with your actual Opportunity ID field name if different.

The screenshot shows a data pipeline with three nodes: 'Sunnies Opportunity', 'SnapshotDate & Compound Key', and 'Write Node'. The 'SnapshotDate & Compound Key' node is selected, showing its configuration and a data preview.

**TRANSFORM**  
SnapshotDate & Compound Key

1. **SnapshotDate\_\_c**  
Calculate values: `date_add(current_date(), -30)`

2. **Compound Id**  
Calculate values: `CONCAT(Id__c, SnapshotDate_c)`

**Preview** Columns

| se   |                            | 2026-05-07T15:22:22.000Z |                        |                          |                        |                                      | 006Nw0000Qkd5eiAB202  |            |
| se   |                            | 2026-05-07T15:22:30.000Z |                        |                          |                        |                                      | 006Nw0000QkdEOIAZ202  |            |

Transform node: (1) `Snapshot Date = current_date()`, (2) `Compound Id = concat(Id__c, Snapshot_Date)`. Preview shows `CrossJoinKey = 1`, `Snapshot Date` and `Compound Id` populated on all rows.

**Date formula syntax note:** In the Batch Data Transform formula editor, use:

- `current_date()` — for today's date (permanent daily formula)
- `current_date() - INTERVAL 1 MONTH` — for one month back (backfill use only)
- `current_date() - INTERVAL N DAY` — for N days back (backfill use only)

**Do NOT** use `DATE()`, `toDate()`, or `date_add()` — these either fail validation or produce blank preview values in this formula editor.

### 3c — Write Node

Click the purple circle node. Configure as follows:

- Click **Use Existing**
- Data Lake Object Name: **Snapshot Store**
- Write Mode: **Upsert**

The field mapping table will populate. Confirm these mappings are present, then click **Apply**:

| Batch Data Transform | Snapshot Store |
|----------------------|----------------|
| Opportunity ID       | Id             |
| Amount               | Amount         |
| Stage                | Stage          |
| CrossJoinKey         | CrossKeyJoin   |
| Snapshot Date        | Snapshot Date  |
| Compound Id          | Compound Id    |

**Upsert behavior:** The upsert key is determined by the primary key on the target DLO. Since **Compound Id** is the primary key on the Snapshot Store, the upsert write honors it automatically — same opportunity + same date updates the existing row; same opportunity + new date inserts a new row. No additional configuration is needed in the Write node.

Write node: Use Existing selected, Snapshot Store as target, Upsert write mode, field mapping table with all six fields mapped.

### 3d — Save and Run

**Save:** Click **Save** in the top right of the transform editor. The Run option is not available from within the editor itself.

**Run:** Return to the Data Transforms list view: Data Cloud Setup → More → **Data Transforms** → [find your transform] → dropdown chevron → **Run Now**. Alternatively, open the saved transform detail view (not the editor) and use Run Now from there.

A dialog appears with a "Run with all data" checkbox:

- For the **initial run and all backfill runs**: check "Run with all data" to ensure all existing rows are processed.
- For **scheduled daily runs**: leave unchecked (incremental mode is sufficient for new data).

After the run completes, verify in Data Lake Objects → Snapshot Store → **Preview**:

- Row count matches your Opportunity count
- Snapshot Date column shows today's date on every row
- Compound Id column is populated
- CrossKeyJoin column shows 1 on every row

## Step 4 — Seed a Second Snapshot Date & Set Schedule

**The bootstrap requirement:** The waterfall needs at least two distinct snapshot dates to show any movement. After your first run, you have one date. You need a second.

#### OPTION A

##### Wait

Set the daily schedule (below) and run again tomorrow. On day 2, select the two dates as your parameters in Tableau Next.

#### OPTION B

##### Backfill immediately

Recommended for demos — temporarily stamp a past date, run, then restore `current_date()`. Steps below.

#### Option B — Backfill immediately (recommended for demos):

1. Open the transform → click the **Transform** node
2. Edit the Snapshot Date formula: change `current_date()` to `current_date() - INTERVAL 1 MONTH`
3. Save → Run Now → check **Run with all data**
4. Wait for completion
5. Edit the formula back to `current_date()`
6. Save → Run Now → check **Run with all data**
7. Verify in the Snapshot Store Preview: you should now see 2 distinct dates in the Snapshot Date column and approximately 2× your Opportunity count in total rows

#### Set the daily schedule:

Data Transforms → find your transform → dropdown → **Schedule**

**Schedule Data Transform**

*If a scheduled transform doesn't finish running before another instance of it is set to begin, then the second instance doesn't run.*

**Run Mode**  
Manual Scheduled

**\* Definition**  
Snapshot Opportuni...

**\* Frequency**  
Hours Days

**\* Run Every**  
1 Days  
The schedule begins on the first day of the month. [Learn more](#)

**\* Start Time**  
2:00 AM

**\* Time Zone**  
America/Los\_Angeles (GMT-07:00)

Cancel Save

*Schedule Data Transform dialog: Run Mode = Scheduled, Frequency = Days, Run Every = 1.*

- Run Mode: **Scheduled**
- Frequency: Days
- Run Every: 1
- Start Time: choose a time after your nightly Salesforce sync completes (typically 2–4 AM in your org's timezone)
- Save

From this point the transform is fully automated. Every morning it adds a new dated layer to the Snapshot Store. After 30 days you have 30 distinct snapshots — select any two dates in Tableau Next and the waterfall recomputes automatically.

Build the waterfall visualization — semantic model, cross-join labels, calculated fields, and chart configuration.

## Step 5 — Create the Waterfall Labels Data Object

The waterfall uses a 9-row lookup table to define bar labels and ordering. This is a static CSV uploaded once and joined to the Snapshot Store in the semantic model.

**Critical:** The CSV requires **three columns** — **Points**, **Label**, and **Cross\_Join\_Key**. The **Cross\_Join\_Key** column (all values = 1) is required for the SDM join. A two-column CSV will produce a broken join and zero values on all bars.

Create a file named `waterfall_labels.csv` with exactly this content:

`waterfall_labels.csv`

CSV

```
Points,Label,Cross_Join_Key
1,Last Month Pipeline,1
2,Qualification,1
3,Needs Analysis,1
4,Proposal/Price Quote,1
5,Negotiation/Review,1
6,Closed Won,1
7,Closed Lost,1
8,Value Proposition,1
9,This Month Pipeline,1
```

**Note on bar labels:** Bars 2–8 (middle bars) are driven by **Stage name** in this implementation. If your org has a meaningful Opportunity Type field with values like 'New Business', 'Organic Growth', 'Contract Renewal', adapt the labels and Step 8 formulas accordingly. Check your actual data first — bars mapped to non-existent values will show zero.

### Upload to Data Cloud:

1. Data Cloud Setup → **Data Streams** → **New** → **File Upload**
2. Upload the CSV. Name the stream `waterfall_labels`
3. Accept auto-detected schema — confirm **Points** = Number, **Label** = Text, **Cross\_Join\_Key** = Number
4. Data Lake Objects → **New** → **Create from Existing** → select `waterfall_labels` stream
5. Name the DLO `waterfall_labels`
6. Data Spaces → [your data space] → **Add Objects** → `waterfall_labels`

**Do NOT** include `waterfall_labels` in the Snapshot Transform — it is a static lookup table, not snapshot data.

## Step 6 — Build the Semantic Data Model

In Tableau Next → **New** → **Semantic Model**. Name it **Pipeline Waterfall** (or **Pipeline Snapshot**).

### 1 Add both data objects

Add **Snapshot Store** as the primary data object. Add **Pipeline Waterfall Labels.csv** as a second data object.

**Important — the cross-join key must be a physical field.** In the Tableau Next SDM, you cannot create a calculated field scoped to a specific data object. The **New ▼** button creates global calculated fields only. The **+** button on each table circle opens the JOIN dialog, not an add-field dialog. The cross-join key must be a physical field on both DLOs — which is why you added CrossJoinKey to the Opportunity DLO in Step 1 and included Cross\_Join\_Key in the waterfall\_labels CSV in Step 5.

### 2 Create the cross-join relationship

Click the relationship line between the two table circles on the canvas. In the join dialog:

- Left field (Pipeline Waterfall Labels.csv): **Cross Join Key**
- Operator: **=**
- Right field (Snapshot Store): **CrossKeyJoin**
- Cardinality: **One** (Labels) to **Many** (Snapshot Store)

Click **Update** → **Apply**.

The screenshot displays the Tableau Next Semantic Data Model (SDM) interface. The top bar shows the model name "Pipeline Waterfall" and a "Share" button. The left sidebar contains a "Model" section with a "New" button and a list of objects: "Calculated Fields (1)", "Parameters (2)", and "Data Objects (2)". The "Data Objects" list includes "Pipeline Waterfall Labels.c..." (10) and "Snapshot Store (10)". The main canvas shows two data object circles connected by a relationship line. The "Pipeline Waterfall Labels.c..." circle is on the left, and the "Snapshot Store" circle is on the right. A relationship dialog box is open, titled "RELATIONSHIP Pipeline Waterfall Labels.csv : Snapshot Store". It shows the "Select Matching Data Object Fields" section with the following fields and operator:

| Field          | Operator | Field        |
|----------------|----------|--------------|
| Cross Join Key | =        | CrossKeyJoin |

The "Cardinality Type" is set to "One" to "Many". The "Match Case Insensitive" checkbox is checked. The "Update" button is highlighted. Below the dialog, a table shows the data objects and their fields:

| Data Source | A <sub>3</sub> Points | A <sub>3</sub> Label |
|-------------|-----------------------|----------------------|
| loadedFiles | 1.0000000000000000    | Last Month P         |
| loadedFiles | 2.0000000000000000    | Qualification        |
| loadedFiles | 3.0000000000000000    | Needs Analy          |
| loadedFiles | 4.0000000000000000    | Proposal/Pric        |
| loadedFiles | 5.0000000000000000    | Negotiation/f        |
| loadedFiles | 6.0000000000000000    | Closed Won           |

SDM join dialog: Pipeline Waterfall Labels.csv.Cross Join Key = Snapshot Store.CrossKeyJoin, Cardinality One to Many.  
Canvas shows the join line connecting the two data objects.

## Step 7 — Create Parameters

In the SDM left panel → **Parameters** (+) → add two date parameters:

| Parameter Name    | Type                | Default Value                   |
|-------------------|---------------------|---------------------------------|
| Select Last Month | Date — single value | Your "last month" snapshot date |
| Select This Month | Date — single value | Your "this month" snapshot date |

Parameter names are case-sensitive. Use exactly **Select Last Month** and **Select This Month** — all formulas reference `[Parameters].[Select Last Month]` and `[Parameters].[Select This Month]`.

**Default values must exactly match dates in your Snapshot Store.** If the parameter date doesn't match any Snapshot Date value in the DLO, **all bars return zero with no error message.** Verify your snapshot dates in Data Lake Objects → Snapshot Store → Preview before setting defaults.

# Step 8 — Create Calculated Fields

Click **New ▼** → **Calculated Field** for each field below.

**Before writing formulas:**

- Use **ELSE 0.0** (not **ELSE 0**) throughout. The Amount field is typed as Currency/Decimal — integer literals cause a type mismatch validation error.
- Never write **-[Amount]**. Always write **[Amount] \* -1**. The semantic layer rejects unary negation.
- If your Amount field is typed as Currency in the DLO and you see a **"missing conversion rates"** error in the SDM, go to the Amount field properties in the SDM and change the Data Type from Currency to Number.
- Use **[Snapshot Store].[field name]** syntax to reference Snapshot Store fields. Use **[Pipeline Waterfall Labels.csv].[field name]** for label fields.

**Last Month Pipeline**

Measure · Number

```
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select Last Month]
THEN [Snapshot Store].[Amount]
ELSE 0.0
END
```

Total pipeline value at the "last month" date.

**This Month Pipeline**

Measure · Number

```
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
THEN [Snapshot Store].[Amount]
ELSE 0.0
END
```

Total pipeline value at the "this month" date.

## Waterfall Values — Field Type: Measure, Data Type: Number

This single CASE field drives all 9 bars. It switches on the **Label string** from the waterfall\_labels table.

**Why Label strings and not Points integers?** Points values ingested from CSV become floats

(1.000000000000000000). The SDM only supports Dimension (Text) or Measure (Number) field types — there is no Dimension + Number combination. Integer comparisons against float Points values silently return zero. Using Label strings avoids this entirely.

*Edit Calculated Field dialog: Field Type = Measure, Data Type = Number, Name = Waterfall Values, formula switching on [Pipeline Waterfall Labels.csv].[Label].*

```

CASE [Pipeline Waterfall Labels.csv].[Label]
WHEN 'Last Month Pipeline' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select Last Month]
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'Qualification' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
AND [Snapshot Store].[Stage] = 'Qualification'
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'Needs Analysis' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
AND [Snapshot Store].[Stage] = 'Needs Analysis'
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'Proposal/Price Quote' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
AND [Snapshot Store].[Stage] = 'Proposal/Price Quote'
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'Negotiation/Review' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
AND [Snapshot Store].[Stage] = 'Negotiation/Review'
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'Closed Won' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select Last Month]
AND [Snapshot Store].[Stage] = 'Closed Won'
THEN [Snapshot Store].[Amount] * -1 ELSE 0.0 END
WHEN 'Closed Lost' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select Last Month]
AND [Snapshot Store].[Stage] = 'Closed Lost'
THEN [Snapshot Store].[Amount] * -1 ELSE 0.0 END
WHEN 'Value Proposition' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
AND [Snapshot Store].[Stage] = 'Value Proposition'
THEN [Snapshot Store].[Amount] ELSE 0.0 END
WHEN 'This Month Pipeline' THEN
IF [Snapshot Store].[Snapshot Date] = [Parameters].[Select This Month]
THEN [Snapshot Store].[Amount] ELSE 0.0 END
ELSE 0.0
END

```

**Adapting for different Stage values:** Replace the stage strings ('Qualification', 'Needs Analysis', etc.) with the exact values in your customer's data. Stage strings are **case-sensitive**. Verify in Data Lake Objects → Snapshot Store → Preview before building formulas.

## Waterfall Color — Field Type: Dimension, Data Type: Text

## Waterfall Color

Dimension · Text

```
IF [Pipeline Waterfall Labels.csv].[Label] = 'Last Month Pipeline'  
OR [Pipeline Waterfall Labels.csv].[Label] = 'This Month Pipeline'  
THEN 'Total'  
ELSEIF [Pipeline Waterfall Labels.csv].[Label] = 'Closed Won'  
OR [Pipeline Waterfall Labels.csv].[Label] = 'Closed Lost'  
THEN 'Outflow'  
ELSE 'Inflow'  
END
```

Categorizes each bar for color encoding: **Total** (start/end bars), **Outflow** (Closed Won / Closed Lost), and **Inflow** (all stage bars). Click **Validate** before saving each field. Save the SDM.

### Verify in the SDM Test panel before building the visualization:

Click **Test** → add these to the Outline:

- Dimension: `Snapshot Store.Snapshot Date, Pipeline Waterfall Labels.csv.Label`
- Measure: `Waterfall Values`

Click **Run**. You should see one row per label per snapshot date, with Waterfall Values returning real dollar amounts for the matching date/stage combinations and `0.0` for non-matching rows. Both snapshot dates should appear with labels populated.

If Waterfall Values shows `0` for all rows, check that parameter default dates exactly match the dates in your Snapshot Store.

# Step 9 — Build the Visualization

Click **Create Visualization** (top right of the SDM).

## 1 Set mark type to Bar

Mark type → **Bar**.

## 2 Columns shelf — Label, sorted by Points

Drag **Label** (from Pipeline Waterfall Labels.csv) to Columns. Right-click the Label pill → **Sort** → By Field → **Points** → Ascending. This locks the x-axis order: Last Month Pipeline → stage bars → This Month Pipeline.

## 3 Rows shelf — Waterfall Values

Drag **Waterfall Values** to Rows → confirm it shows as **SUM(Waterfall Values)**.

## 4 Apply color encoding

Drag **Waterfall Color** to the Color shelf. Assign hex colors:

| Category  | Hex     | Bars                                     |
|-----------|---------|------------------------------------------|
| ■ Total   | #747474 | Last Month Pipeline, This Month Pipeline |
| ■ Inflow  | #3BA755 | Stage bars (green)                       |
| ■ Outflow | #EA001E | Closed Won, Closed Lost (red)            |

## 5 Add date pickers

Drag **Select Last Month** and **Select This Month** parameters onto the canvas. These become the interactive date selectors shown at the top of the dashboard.

## 6 Save

The result: inflow bars rise above zero, outflow bars fall below zero. The CASE formula handles directionality — no floating bar encoding required.

Final Pipeline Waterfall: Select Last Month / Select This Month date pickers, gray total bars, green stage bars (Qualification / Needs Analysis / Proposal-Price Quote / Value Proposition), red bars for Closed Won and Closed Lost.

## Validation — Does Your Waterfall Balance?

Before sharing with stakeholders, verify with this identity. Build a plain table in the visualization with **Label** on Rows and **SUM(Waterfall Values)** as the measure. Sum all 9 rows. The total must equal **This Month Pipeline**.

| Balance Identity                                                                                                                                                                                                                                                                                                             | Verification                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Last Month Pipeline (positive – bar 1)<br>+ Qualification (positive – bar 2)<br>+ Needs Analysis (positive – bar 3)<br>+ Proposal/Price Quote (positive – bar 4)<br>+ Negotiation/Review (positive – bar 5)<br>+ Closed Won (negative – bar 6)<br>+ Closed Lost (negative – bar 7)<br>+ Value Proposition (positive – bar 8) |  |
| = This Month Pipeline (positive – bar 9)                                                                                                                                                                                                                                                                                     |                                                                                   |

**If they don't balance:** the most common causes are a parameter date that doesn't match a stored Snapshot Date (all bars zero), a Stage string that doesn't match the DLO exactly (a stage bar zero), or the Last Month Pipeline branch pointing at the This Month parameter (bars 1 and 9 identical). See the Troubleshooting Reference on the next page.

## Troubleshooting Reference

| Symptom                                 | Cause                                                                    | Fix                                                                              |
|-----------------------------------------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| All bars zero                           | Parameter dates don't match any SnapshotDate in DLO                      | Verify exact dates in Snapshot Store Preview; update parameter defaults to match |
| Bars 1 and 9 identical                  | Waterfall Values WHEN 'Last Month Pipeline' using This Month parameter   | Change condition to [Parameters].[Select Last Month]                             |
| Stage bars all zero                     | Stage strings in formula don't match DLO values exactly                  | Check case-sensitive Stage values in Snapshot Store Preview                      |
| Outflow bars zero                       | Stage = 'Closed Won' / 'Closed Lost' not matching                        | Verify stage string case exactly matches DLO values                              |
| Type mismatch error                     | ELSE 0 (integer) conflicts with decimal/currency Amount field            | Change all ELSE 0 to ELSE 0.0 throughout Waterfall Values                        |
| Currency conversion error in SDM        | Amount typed as Currency, org missing conversion rates                   | Change Amount field Data Type from Currency to Number in SDM field properties    |
| Syntax error on Points comparison       | Points ingested as float — integer comparison fails                      | Use Label string comparisons instead of Points integer comparisons               |
| CrossJoinKey null on some rows          | Transform ran before CrossJoinKey was mapped in Write node               | Re-run transform with "Run with all data" checked                                |
| Write node field not visible in mapping | Target DLO field didn't exist when Write node was opened                 | Add the field to the DLO first, then reopen the Write node                       |
| Run button not visible from editor      | Transform must be run from the list view, not the editor                 | Data Transforms list → dropdown chevron → Run Now                                |
| "Data Transforms" menu not found        | Wrong search term — UI says "Data Transforms" not "Data Transformations" | Navigate via More menu in Data Cloud Setup                                       |
| Direct URL permissions error            | <code>/lightning/o/DataTransformation/home is invalid path</code>        | More menu navigation only                                                        |
| Viz save NullPointerException           | Multiple separate SDM measures each referencing parameters (API v66 bug) | Use single Waterfall Values CASE field — do not create 9 separate measures       |

# Schema Field Reference

Confirm these fields exist in the Snapshot Store before building SDM formulas.

| Field         | Used For                           | Notes                                                                                    |
|---------------|------------------------------------|------------------------------------------------------------------------------------------|
| Snapshot Date | Filtering to Last/This Month dates | Date type. Added manually during DLO creation.                                           |
| Compound Id   | Upsert primary key                 | Text (255). Format: <b>OpportunityId + SnapshotDate</b>                                  |
| CrossKeyJoin  | Cross-join to waterfall_labels     | Number, value = 1 on every row. Required for SDM join.                                   |
| Id            | Opportunity identifier             | Text. From source Opportunity DLO.                                                       |
| Amount        | All waterfall bar values           | Currency or Number. If Currency, change to Number in SDM to avoid conversion rate error. |
| Stage         | Classifying bar 2–8 conditions     | Text. Values must match CASE string literals exactly — case-sensitive.                   |

## Daily Operations (Post-Setup)

Once the schedule is set, no manual intervention is needed:

- **Every morning:** the transform runs — today's opportunities are written to the Snapshot Store with today's SnapshotDate.
- **In Tableau Next:** update the Select Last Month and Select This Month parameters to your desired comparison dates.
- **After 30 days:** 30 distinct snapshot dates are available — pick any two for a month-over-month comparison.
- **Backfilling historical data:** temporarily set the SnapshotDate formula to a past date, run with **Run with all data** checked, then restore **current\_date()**.
